Printed in the United States of America

Contents:

Chapter 1: Smarandache Function applied to perfect numbers

Chapter 2: A result obtained using the Smarandache Function

Chapter 3: A Congruence with the Smarandache Function

Chapter 4: A functional recurrence to obtain the prime numbers using the Smarandache prime function

Chapter 5: The general term of the prime number sequence and the Smarandache prime function

Chapter 6: Expressions of the Smarandache Coprime Function

Chapter 7: New Prime Numbers

Chapter 1: Smarandache function applied to perfect numbers

The Smarandache function is defined as follows:

$S(n)$ = the smallest positive integer such that $S(n)!$ is divisible by n . [1]

In this article we are going to see that the value this function takes when n is a perfect number of the form $n = 2^{k-1} \cdot (2^k - 1)$, $p = 2^k - 1$ being a prime number.

Lemma 1: Let $n = 2^i \cdot p$ when p is an odd prime number and i an integer such that:

$$0 \leq i \leq E\left(\frac{p}{2}\right) + E\left(\frac{p}{2^2}\right) + E\left(\frac{p}{2^3}\right) + \dots + E\left(\frac{p}{2^{E(\log_2 p)}}\right) = e_2(p!)$$

where $e_2(p!)$ is the exponent of 2 in the prime number decomposition of $p!$.

$E(x)$ is the greatest integer less than or equal to x .

One has that $S(n) = p$.

Demonstration:

Given that $GCD(2^i, p) = 1$ (GCD= greatest common divisor) one has that

$S(n) = \max\{S(2^i), S(p)\} \geq S(p) = p$. Therefore $S(n) \geq p$.

If we prove that $p!$ is divisible by n then one would have the equality.

$$p! = p_1^{e_{p_1}(p!)} \cdot p_2^{e_{p_2}(p!)} \cdot \dots \cdot p_s^{e_{p_s}(p!)}$$

where p_i is the i -th prime of the prime number decomposition of $p!$. It is clear that

$p_1 = 2$, $p_s = p$, $e_{p_s}(p!) = 1$ for which:

$$p! = 2^{e_2(p!)} \cdot p_2^{e_{p_2}(p!)} \cdot \dots \cdot p_{s-1}^{e_{p_{s-1}}(p!)} \cdot p$$

From where one can deduce that:

$$\frac{p!}{n} = 2^{e_2(p!)-i} \cdot p_2^{e_{p_2}(p!)} \dots p_{s-1}^{e_{p_{s-1}}(p!)}$$

is a positive integer since $e_2(p!) - i \geq 0$.

Therefore one has that $S(n) = p$

Proposition1: If n is a perfect number of the form $n = 2^{k-1} \cdot (2^k - 1)$ with k is a positive integer, $2^k - 1 = p$ prime, one has that $S(n) = p$.

Demonstration:

For the Lemma it is sufficient to prove that $k - 1 \leq e_2(p!)$.

If we can prove that:

$$k - 1 \leq 2^{k-1} - \frac{1}{2} \quad (1)$$

we will have proof of the proposition since:

$$k - 1 \leq 2^{k-1} - \frac{1}{2} = \frac{2^k - 1}{2} = \frac{p}{2}$$

As $k - 1$ is an integer one has that $k - 1 \leq E\left(\frac{p}{2}\right) \leq e_2(p!)$

Proving (1) is the same as proving $k \leq 2^{k-1} + \frac{1}{2}$ at the same time, since k is integer, is equivalent to proving $k \leq 2^{k-1}$ (2).

In order to prove (2) we may consider the function: $f(x) = 2^{x-1} - x$ x real number.

This function may be derived and its derivate is $f'(x) = 2^{x-1} \ln 2 - 1$.

f will be increasing when $2^{x-1} \ln 2 - 1 > 0$ resolving x:

$$x > 1 - \frac{\ln(\ln 2)}{\ln 2} \cong 1.5287$$

In particular f will be increasing $\forall x \geq 2$.

Therefore $\forall x \geq 2$ $f(x) \geq f(2) = 0$ that is to say $2^{x-1} - x \geq 0 \quad \forall x \geq 2$.

Therefore: $2^{k-1} \geq k \forall k \geq 2$ integer.

And thus is proved the proposition.

EXAMPLES:

$6 = 2 \cdot 3$	$S(6)=3$
$28 = 2^2 \cdot 7$	$S(28)=7$
$496 = 2^4 \cdot 31$	$S(496)=31$
$8128 = 2^6 \cdot 127$	$S(8128)=127$

Chapter 2: A result obtained using the Smarandache Function

Smarandache Function is defined as followed:

$S(m)$ =The smallest positive integer so that $S(m)!$ is divisible by m . [1]

Let's see the value which such function takes for $m = p^{n^k}$ with n integer, $n \geq 2$ and p prime number. To do so a Lemma required.

Lemma 1 $\forall m, n \in \mathbb{N} \quad m, n \geq 2$

$$m^n = E\left[\frac{m^{n+1} - m^n + m}{m}\right] + E\left[\frac{m^{n+1} - m^n + m}{m^2}\right] + \dots + E\left[\frac{m^{n+1} - m^n + m}{m^{E[\log_m(m^{n+1} - m^n + m)]}}\right]$$

where $E(x)$ gives the greatest integer less than or equal to x .

Proof:

Let's see in the first place the value taken by $E[\log_m(m^{n+1} - m^n + m)]$.

If $n \geq 2$: $m^{n+1} - m^n + m < m^{n+1}$ and therefore

$$\log_m(m^{n+1} - m^n + m) < \log_m m^{n+1} = n + 1.$$

And if $m \geq 2$:

$$\begin{aligned} mm^n \geq 2m^n &\Rightarrow m^{n+1} \geq 2m^n \Rightarrow m^{n+1} + m \geq 2m^n \Rightarrow m^{n+1} - m^n + m \geq m^n \\ &\Rightarrow \log_m(m^{n+1} - m^n + m) \geq \log_m m^n = n \Rightarrow E[\log_m(m^{n+1} - m^n + m)] \geq n \end{aligned}$$

As a result: $n \leq E[\log_m(m^{n+1} - m^n + m)] < n + 1$ therefore:

$$E[\log_m(m^{n+1} - m^n + m)] = n \quad \text{if } n, m \geq 2$$

Now let's see the value which it takes for $1 \leq k \leq n$: $E\left[\frac{m^{n+1} - m^n + m}{m^k}\right]$

$$E\left[\frac{m^{n+1} - m^n + m}{m^k}\right] = E\left[m^{n+1-k} - m^{n-k} + \frac{1}{m^{k-1}}\right]$$

$$\text{If } k=1: E\left[\frac{m^{n+1} - m^n + m}{m^k}\right] = m^n - m^{n-1} + 1$$

$$\text{If } 1 < k \leq n: E\left[\frac{m^{n+1} - m^n + m}{m^k}\right] = m^{n+1-k} - m^{n-k}$$

Let's see what is the value of the sum:

$$k=1 \quad m^n \quad -m^{n-1} \quad \dots \quad \dots \quad \dots \quad \dots \quad +1$$

$$k=2 \quad \quad m^{n-1} \quad -m^{n-2}$$

$$k=3 \quad \quad \quad m^{n-2} \quad -m^{n-3}$$

$$\cdot \quad \quad \quad \cdot$$

$$\cdot \quad \quad \quad \cdot$$

$$\cdot \quad \quad \quad \cdot$$

$$k=n-1 \quad \quad \quad \cdot \quad \quad \quad m^2 \quad -m$$

$$k=n \quad \quad \quad \quad \quad \quad m \quad -1$$

Therefore:

$$\sum_{k=1}^n E\left[\frac{m^{n+1} - m^n + m}{m^k}\right] = m^n \quad m, n \geq 2$$

Proposition: $\forall p$ prime number $\forall n \geq 2$:

$$S(p^{p^n}) = p^{n+1} - p^n + p$$

Proof:

Having $e_p(k)$ = exponent of the prime number p in the prime decomposition of k .

We get:

$$e_p(k) = E\left(\frac{k}{p}\right) + E\left(\frac{k}{p^2}\right) + E\left(\frac{k}{p^3}\right) + \dots + E\left(\frac{k}{p^{E(\log_p k)}}\right)$$

And using the lemma we have

$$e_p \left[(p^{n+1} - p^n + p)! \right] = E \left[\frac{p^{n+1} - p^n + p}{p} \right] + E \left[\frac{p^{n+1} - p^n + p}{p^2} \right] + \dots + E \left[\frac{p^{n+1} - p^n + p}{p^{E \left[\log_p (p^{n+1} - p^n + p) \right]}} \right] = p^n$$

Therefore:

$$\frac{(p^{n+1} - p^n + p)!}{p^{p^n}} \in \mathbb{N} \quad \text{and} \quad \frac{(p^{n+1} - p^n + p - 1)!}{p^{p^n}} \notin \mathbb{N}$$

And :

$$S(p^{p^n}) = p^{n+1} - p^n + p$$

Chapter 3: A Congruence with the Smarandache function

Smarandache's function is defined thus:

$S(n)$ = is the smallest integer such that $S(n)!$ is divisible by n . [1]

In this article we are going to look at the value that has $S(2^k - 1) \pmod{k}$

For all integer, $2 \leq k \leq 97$.

97	13842607235828485645766393	1

One can see from the table that there are only 4 exceptions for $2 \leq k \leq 97$

We can see in detail the 4 exceptions in a table:

$k=28=2^2 \cdot 7$	$S(2^{28}-1) \equiv 15 \pmod{28}$
$k=52=2^2 \cdot 13$	$S(2^{52}-1) \equiv 27 \pmod{52}$
$k=68=2^2 \cdot 17$	$S(2^{68}-1) \equiv 35 \pmod{68}$
$k=92=2^2 \cdot 23$	$S(2^{92}-1) \equiv 47 \pmod{92}$

One can observe in these 4 cases that $k=2^2p$ with p is a prime and more over $S(2^k - 1) \equiv \frac{k}{2} + 1 \pmod{k}$

UNSOLVED QUESTION:

One can obtain a general formula that gives us, in function of k the value $S(2^k - 1) \pmod{k}$ for all positive integer values of k ?

Reference:

[1] Smarandache Notions Journal, Vol. 9, No. 1-2, (1998), pp. 21-26.

Chapter 4: A functional recurrence to obtain the prime numbers using the Smarandache prime function.

Theorem: We are considering the function:

For n integer:

$$F(n) = n + 1 + \sum_{m=n+1}^{2n} \prod_{i=n+1}^m \left[- \frac{\sum_{j=1}^i \left(\left\lfloor \frac{i}{j} \right\rfloor - \left\lfloor \frac{i-1}{j} \right\rfloor \right) - 2}{i} \right]$$

one has: $p_{k+1} = F(p_k)$ for all $k \geq 1$ where $\{p_k\}_{k \geq 1}$ are the prime numbers and $\lfloor x \rfloor$ is the greatest integer less than or equal to x .

Observe that the knowledge of p_{k+1} only depends on knowledge of p_k and the knowledge of the fore primes is unnecessary.

Proof:

Suppose that we have found a function $P(i)$ with the following property:

$$P(i) = \begin{cases} 1 & \text{if } i \text{ is composite} \\ 0 & \text{if } i \text{ is prime} \end{cases}$$

This function is called Smarandache prime function.(Ref.)

Consider the following product:

$$\prod_{i=p_k+1}^m P(i)$$

If $p_k < m < p_{k+1}$ $\prod_{i=p_k+1}^m P(i) = 1$ since $i: p_k + 1 \leq i \leq m$ are all composites.

If $m \geq p_{k+1}$ $\prod_{i=p_k+1}^m P(i) = 0$ since $P(p_{k+1}) = 0$

Here is the sum:

$$\begin{aligned} \sum_{m=p_k+1}^{2p_k} \prod_{i=p_k+1}^m P(i) &= \sum_{m=p_k+1}^{p_{k+1}-1} \prod_{i=p_k+1}^m P(i) + \sum_{m=p_{k+1}}^{2p_k} \prod_{i=p_k+1}^m P(i) = \sum_{m=p_k+1}^{p_{k+1}-1} 1 = \\ &= p_{k+1} - 1 - (p_k + 1) + 1 = p_{k+1} - p_k - 1 \end{aligned}$$

The second sum is zero since all products have the factor $P(p_{k+1}) = 0$.

Therefore we have the following recurrence relation:

$$p_{k+1} = p_k + 1 + \sum_{m=p_k+1}^{2p_k} \prod_{i=p_k+1}^m P(i)$$

Let's now see we can find $P(i)$ with the asked property.

Consider:

$$\left\lfloor \frac{i}{j} \right\rfloor - \left\lfloor \frac{i-1}{j} \right\rfloor = \begin{cases} 1 & \text{si } j \mid i \\ 0 & \text{si } j \text{ not } \mid i \end{cases} \quad j = 1, 2, \dots, i \quad i \geq 1$$

We deduce of this relation:

$$d(i) = \sum_{j=1}^i \left\lfloor \frac{i}{j} \right\rfloor - \left\lfloor \frac{i-1}{j} \right\rfloor$$

where $d(i)$ is the number of divisors of i .

If i is prime $d(i) = 2$ therefore:

$$-\left\lfloor -\frac{d(i)-2}{i} \right\rfloor = 0$$

If i is composite $d(i) > 2$ therefore:

$$0 < \frac{d(i)-2}{i} < 1 \Rightarrow -\left\lfloor -\frac{d(i)-2}{i} \right\rfloor = 1$$

Therefore we have obtained the Smarandache Prime Function $P(i)$ which is:

$$P(i) = -\left\lfloor -\frac{\sum_{j=1}^i \left(\left\lfloor \frac{i}{j} \right\rfloor - \left\lfloor \frac{i-1}{j} \right\rfloor \right) - 2}{i} \right\rfloor \quad i \geq 2 \text{ integer}$$

With this, the theorem is already proved .

Chapter 5: The general term of the prime number sequence and the Smarandache prime function.

Let us consider the function $d(i)$ = number of divisors of the positive integer number i . We have found the following expression for this function:

$$d(i) = \sum_{k=1}^i E\left(\frac{i}{k}\right) - E\left(\frac{i-1}{k}\right)$$

“ $E(x) = \text{Floor}[x]$ ”

We proved this expression in the article “A functional recurrence to obtain the prime numbers using the Smarandache Prime Function”.

We deduce that the following function:

$$G(i) = -E\left[-\frac{d(i)-2}{i}\right]$$

This function is called the Smarandache Prime Function (Reference)

It takes the next values:

$$G(i) = \begin{cases} 0 & \text{if } i \text{ is prime} \\ 1 & \text{if } i \text{ is composite} \end{cases}$$

Let us consider now $\pi(n)$ = number of prime numbers smaller or equal than n .

It is simple to prove that:

$$\pi(n) = \sum_{i=2}^n (1 - G(i))$$

Let us have too:

$$\begin{aligned} \text{If } 1 \leq k \leq p_n - 1 &\Rightarrow E\left(\frac{\pi(k)}{n}\right) = 0 \\ \text{If } C_n \geq k \geq p_n &\Rightarrow E\left(\frac{\pi(k)}{n}\right) = 1 \end{aligned}$$

We will see what conditions have to carry C_n .

Therefore we have the following expression for p_n n-th prime number:

$$p_n = 1 + \sum_{k=1}^{C_n} \left(1 - E\left(\frac{\pi(k)}{n}\right)\right)$$

If we obtain C_n that only depends on n , this expression will be the general term of the prime numbers sequence, since π is in function with G and G does with $d(i)$ that is expressed in function with i too. Therefore the expression only depends on n .

Let us consider $C_n = 2(E(n \log n) + 1)$

Since $p_n \approx n \log n$ from a certain n_0 it will be true that

$$(1) \quad p_n \leq 2(E(n \log n) + 1)$$

If n_0 it is not too big, we can prove that the inequality is true for smaller or equal values than n_0 .

It is necessary to that:

$$E\left[\frac{\pi(2(E(n \log n) + 1))}{n}\right] = 1$$

If we check the inequality:

$$(2) \quad \pi(2(E(n \log n) + 1)) < 2n$$

We will obtain that:

$$\frac{\pi(C_n)}{n} < 2 \Rightarrow E\left[\frac{\pi(C_n)}{n}\right] \leq 1 \quad ; \quad C_n \geq p_n \Rightarrow E\left[\frac{\pi(C_n)}{n}\right] = 1$$

We can experimentally check this last inequality saying that it checks for a lot of values and the difference tends to increase, wich makes to think that it is true for all n .

Therefore if we prove that the (1) and (2) inequalities are true for all n which seems to be very probable; we will have that the general term of the prime numbers sequence is:

$$p_n = 1 + \sum_{k=1}^{2(E(n \log n)+1)} \left[1 - E \left[\frac{\sum_{j=2}^k \left[1 + E \left[- \frac{\sum_{s=1}^j (E(j/s) - E((j-1)/s)) - 2}{j} \right]}{n} \right]}{n} \right] \right]$$

Chapter 6: Expressions of the Smarandache Coprime Function

Smarandache Coprime function is defined this way:

$$C_k(n_1, n_2, \dots, n_k) = \begin{cases} 0 & \text{if } n_1, n_2, \dots, n_k \text{ are coprime numbers} \\ 1 & \text{otherwise} \end{cases}$$

We see two expressions of the Smarandache Coprime Function for $k=2$.

EXPRESSION 1:

$$C_2(n_1, n_2) = \left\lfloor -\frac{n_1 n_2 - \text{lcm}(n_1, n_2)}{n_1 n_2} \right\rfloor$$

$\lfloor x \rfloor$ = the biggest integer number smaller or equal than x .

If n_1, n_2 are coprime numbers:

$$\text{lcm}(n_1, n_2) = n_1 n_2 \quad \text{therefore:} \quad C_2(n_1, n_2) = \left\lfloor \frac{0}{n_1 n_2} \right\rfloor = 0$$

If n_1, n_2 aren't coprime numbers:

$$\text{lcm}(n_1, n_2) < n_1 n_2 \Rightarrow 0 < \frac{n_1 n_2 - \text{lcm}(n_1, n_2)}{n_1 n_2} < 1 \Rightarrow C_2(n_1, n_2) = 1$$

EXPRESSION 2:

$$C_2(n_1, n_2) = 1 + \left\lfloor -\frac{\prod_{\substack{d|n_1 \\ d>1}} \prod_{\substack{d'|n_2 \\ d'>1}} |d - d'|}{\prod_{d|n_1} \prod_{d'|n_2} (d + d')} \right\rfloor$$

If n_1, n_2 are coprime numbers then $d \neq d' \quad \forall d, d' \neq 1$

$$\Rightarrow 0 < \frac{\prod_{d|n_1} \prod_{d'|n_2} |d - d'|}{\prod_{d>1} \prod_{d'>1} (d + d')} < 1 \Rightarrow C_2(n_1, n_2) = 0$$

If n_1, n_2 aren't coprime numbers $\exists d = d' \quad d > 1, d' > 1 \Rightarrow C_2(n_1, n_2) = 1$

EXPRESSION 3:

Smarandache Coprime Function for $k \geq 2$:

$$C_k(n_1, n_2, \dots, n_k) = \left\lfloor \frac{1}{GCD(n_1, n_2, \dots, n_k)} - 1 \right\rfloor$$

If n_1, n_2, \dots, n_k are coprime numbers:

$$GCD(n_1, n_2, \dots, n_k) = 1 \Rightarrow C_k(n_1, n_2, \dots, n_k) = 0$$

If n_1, n_2, \dots, n_k aren't coprime numbers: $GCD(n_1, n_2, \dots, n_k) > 1$

$$0 < \frac{1}{GCD} < 1 \Rightarrow \left\lfloor \frac{1}{GCD} - 1 \right\rfloor = 1 = C_k(n_1, n_2, \dots, n_k)$$

Chapter 7: New Prime Numbers

I have found some new prime numbers using the PROTH program of Yves Gallot.

This program is based on the following theorem:

Proth Theorem (1878):

Let $N = k \cdot 2^n + 1$ where $k < 2^n$. If there is an integer number a so that $a^{\frac{N-1}{2}} \equiv -1 \pmod{N}$ therefore N is prime.

The Proth program is a test for primality of greater numbers defined as $k \cdot b^n + 1$ or $k \cdot b^n - 1$. The program is made to look for numbers of less than 5.000000 digits and it is optimized for numbers of more than 1000 digits..

Using this Program, I have found the following prime numbers:

$3239 \cdot 2^{12345} + 1$	with 3720 digits	$a = 3, a = 7$
$7551 \cdot 2^{12345} + 1$	with 3721 digits	$a = 5, a = 7$
$7595 \cdot 2^{12345} + 1$	with 3721 digits	$a = 3, a = 11$
$9363 \cdot 2^{12321} + 1$	with 3713 digits	$a = 5, a = 7$

Since the exponents of the first three numbers are Smarandache number $Sm(5)=12345$ we can call this type of prime numbers, prime numbers of Smarandache .

Helped by the MATHEMATICA program, I have also found new prime numbers which are a variant of prime numbers of Fermat. They are the following:

$$2^{2^n} \cdot 3^{2^n} - 2^{2^n} - 3^{2^n} \text{ for } n=1, 4, 5, 7 .$$

It is important to mention that for $n=7$ the number which is obtained has 100 digits.

Chris Nash has verified the values $n=8$ to $n=20$, this last one being a number of 815.951 digits, obtaining that they are all composite. All of them have a tiny factor except $n=13$.
